(54) Title: IMMQBILIZED PROTEINS WITH SPECIFIC BINDING CAPACITIES AND THEIR USE IN PROCESSES AND PROD-UCTS

(57) Abstract

A method is provided for immobilizing a binding protein capable of binding to a specific compound, using recombinant DNA techniques for producing said binding protein or a functional part thereof. The binding protein is immobilized by producing it as part of a chimeric protein also comprising an anchoring part derivable from the C-terminal part of an anchoring protein, thereby ensuring that the binding protein is localized in or at the exterior of the cell wall of the host cell. Suitable anchoring proteins are yeast α -agglutinin, FLO1 (a protein associated with the flocculation phenotype in S. cerevisiae), the Major Cell Wall Protein of lower eukaryotes, and a proteinase of lactic acid bacteria. For secretion the chimeric protein can comprise a signal peptide including those of α-mating factor of yeast, α-agglutinin of yeast, invertase of Saccharomyces, inulinase of Kluyveromyces, α-amylase of Bacillus, and proteinase of lactic acid bacteria. Also provided are recombinant polynucleotides encoding such chimeric protein, vectors comprising such polynucleotide, transformed microorganisms having such chimeric protein immobilized on their cell wall, and a process for carrying out an isolation process by using such transformed host, wherein a medium containing said specific compound is contacted with such host cell to form a complex, separating said complex from the medium and, optionally, releasing said specific compound from said binding protein.

Immobilized proteins with specific binding capacities and their use in Title: processes and products

Background of the invention

The pharmaceutical, the fine chemicals and the food industry need a number of compounds that have to be isolated from complex mixtures such as extracts of animal or plant tissue, or fermentation broth. Often these isolation processes determine the price of the product.

Conventional isolation processes are not very specific and during the isolation processes the compound to be isolated is diluted considerably with the consequence that expensive steps for removing water or other solvents have to be applied.

For the isolation of some specific compounds affinity techniques are used. The advantage of these techniques is that the compounds bind very specifically to a 15 certain ligand. However these ligands are quite often very expensive. To avoid spillage of these expensive ligands they can be linked to an insoluble support. However, often linking the ligand is also expensive and, moreover, the functionality of the ligand is often affected negatively by such procedure. So a need exists for developing cheap processes for preparing highly effective immobilized ligands. 20

Summary of the invention

25

The invention provides a method for immobilizing a binding protein capable of binding to a specific compound, comprising the use of recombinant DNA techniques for producing said binding protein or a functional part thereof still having said specific binding capability, said protein or said part thereof being linked to the outside of a host cell, whereby said binding protein or said part thereof is localized in the cell wall or at the exterior of the cell wall by allowing the host cell to produce and secrete a chimeric protein in which said binding protein or said functional part thereof is bound with its C-terminus to the N-terminus of an anchoring part of an 30 anchoring protein capable of anchoring in the cell wall of the host cell, which anchoring part is derivable from the C-terminal part of said anchoring protein.

Preferably, the host is selected from Gram-positive bacteria and fungi, which have a cell wall at the outside of the host cell, in contrast to Gram-negative bacteria and cells of higher eukaryotes such as animal cells and plant cells, which have a membrane at the outside of their cells. Suitable Gram-positive bacteria comprise lactic acid bacteria and bacteria belonging to the genera Bacillus and Streptomyces. Suitable fungi comprise yeasts belonging to the genera Candida, Debaryomyces, Hansenula, Kluyveromyces, Pichia and Saccharomyces, and moulds belonging to the genera Aspergillus, Penicillium and Rhizopus. In this specification the group of fungi comprises the group of yeasts and the group of moulds, which are also known as lower eukaryotes. In contrast to the cells in plants and animals, the group of bacteria and lower eukaryotes are also indicated in this specification as microorganisms. The invention also provides a recombinant polynucleotide capable of being used in a method as described above, such polynucleotide comprising (i) a structural gene encoding a binding protein or a functional part thereof still having the specific binding capability, and (ii) at least part of a gene encoding an anchoring protein capable of anchoring in the cell wall of a Gram-positive bacterium or a fungus, said part of a gene encoding at least the anchoring part of said anchoring protein, which anchoring part is derivable from the C-terminal part of said anchoring protein. The anchoring protein can be selected from a-agglutinin, a-agglutinin, FLO1, the Major Cell Wall Protein of a lower eukaryote, and proteinase of lactic acid bacteria. Preferably, such polynucleotide further comprises a nucleotide sequence encoding a signal peptide ensuring secretion of the expression product of the polynucleotide, which signal peptide can be derived from a protein selected from the α-mating factor of yeast, α-agglutinin of yeast, invertase of Saccharomyces, inulinase of Kluyveromyces, a-amylase of Bacillus, and proteinase of lactic acid bacteria. The polynucleotide can be operably linked to a promoter, which is preferably an inducible promoter.

The invention further provides a recombinant vector comprising a polynucleotide according to the invention, a chimeric protein encoded by a polynucleotide according to the invention, and a host cell having a cell wall at the outside of its cell and containing at least one polynucleotide according to the invention. Preferably at least one polynucleotide is integrated in the chromosome of the host cell. Another

embodiment of this part of the invention is a host cell having a chimeric protein according to the invention immobilized in its cell wall and having the binding protein part of the chimeric protein localized in the cell wall or at the exterior of the cell wall.

Another embodiment of the invention is a process for carrying out an isolation process by using an immobilized binding protein or functional part thereof still capable of binding to a specific compound, wherein a medium containing said specific compound is contacted with a host cell according to the invention under conditions whereby a complex between said specific compound and said immobilized binding protein is formed, separating said complex from the medium originally containing said specific compound and, optionally, releasing said specific compound from said binding protein or functional part thereof.

Brief description of the figures

- In Figure 1 the composition of pEMBL9-derived plasmid pUR4122 is indicated, the preparation of which is described in Example 1.
 - In Figure 2 the composition of plasmid pUR2741 is indicated, which is a derivative of published plasmid pUR2740, see Example 1.
- In Figure 3 the composition of pEMBL9-derived plasmid pUR2968 is indicated. Its preparation is described in Example 1.
 - In Figure 4 the preparation of plasmid pUR4174 starting from plasmids pUR2741, pUR2968 and pUR4122 is indicated, as well as the preparation of plasmid pUR4175 starting from plasmids pSY16, pUR2968 and pUR4122. These preparations are described in Example 1.
- In Figure 5 the composition of plasmid pUR2743.4 is indicated. Its preparation is described in Example 2. It contains the 714 bp *PstI-XhoI* fragment given in SEQ ID N0: 12, which fragment encodes an scFv-TRAS fragment of anti-traseolide® antibody 02/01/01.
 - In Figure 6 the composition of plasmid pUR4178 is indicated. Its preparation is indicated in Example 2. It contains the above mentioned 714 bp *PstI-XhoI* fragment given in SEO ID NO: 12. This plasmid is suitable for the expression of a fusion

protein between scFv-TRAS and α AGG preceded by the invertase signal sequence (SUC2).

In Figure 7 the composition of plasmid pUR4179 is indicated. Its preparation is indicated in Example 2. It contains the above mentioned 714 bp PstI-XhoI fragment given in SEQ ID NO: 12. This plasmid is suitable for the expression of a fusion protein between scFv-TRAS and α AGG preceded by the prepro- α -mating factor signal signal sequence.

In Figure 8 a molecular design picture is given, showing the musk odour molecule traseolide® and a modified musk antigen, described in Example 3.

In Figure 9 the composition of plasmid pUR4177 is indicated. Its construction is described in Example 4. Plasmid pUR4177 contains the 734 bp Eagl-XhoI DNA fragment given in SEQ ID NO: 13 encoding the variable regions of the heavy and light chain fragments from the monoclonal antibody directed against the human chorionic gonadotropin (an scFv-HCG fragment) and is a 2 μm-based vector

suitable for production of the chimeric scFv HCG-aAGG fusion protein preceded by the invertase signal sequence and under the control of the GAL7 promoter.

In Figure 10 the composition of plasmid pUR4180 is indicated. Its preparation is indicated in Example 4. It contains the above mentioned 734 bp Eagl-Xhol DNA fragment given in SEQ ID NO: 13 and is a 2 µm-based vector suitable for

production of the chimeric scFv-HCG-αAGG fusion protein preceded by the preproα-mating factor signal sequence and under the control of the GAL7 promoter. In Figure 11 the composition of plasmid pUR2990, a 2 μm-based vector, is indicated, which is suggested in Example 5 as a starting vector for the preparation of plasmid pUR4196 (see Figure 12). Plasmid pUR2990 contains a DNA fragment

encoding a chimeric lipase-FLO1 protein that will be anchored in the cell wall of a lower eukaryote and can catalyze lipid hydrolysis.

In Figure 12 the composition of plasmid pUR4196 is indicated. Its preparation is explained in Example 5. It contains a DNA fragment encoding a chimeric protein comprising the scFv-HCG followed by the C-terminal part of the FLO1-protein, and is a vector suitable for the production of a chimeric protein anchored in the cell wall of the host organism and can bind HCG.

In Figure 13 the composition of plasmid pUR2985 is indicated. Its preparation is described in Example 6. It contains a *choB* gene coding for the mature part of the cholesterol oxidase (EC 1.1.3.6) obtained via PCR techniques from the chromosome of *Brevibacterium sterolicum*.

- In Figure 14 the composition of plasmid pUR2987 is indicated. Its preparation from plasmid pUR2985 is described in Example 6. It contains a DNA sequence comprising the choB gene coding for the mature part of the cholesterol oxidase preceded by DNA encoding the prepro-α-mating factor signal sequence and followed by DNA encoding the C-terminal part of α-agglutinin.
- In Figure 15 the composition of the published plasmid pGKV550 is indicated. It is described in Example 7 and contains the complete cell wall proteinase operon of Lactococcus lactis subsp. cremoris Wg2, including the promoter, the ribosome binding site and the prtP gene.
- In Figure 16 the composition of plasmid pUR2988 is indicated. Its preparation is

 described in Example 7. It is anticipated that this plasmid can be used for preparing
 a further plasmid pUR2989, which after introduction in a lactic acid bacterium will
 be responsible for producing a chimeric protein that will be anchored at the outer
 surface of the lactic acid bacterium and is capable of binding cholesterol.
- In Figure 17 the composition of plasmid pUR2993 is indicated. Its preparation is
 described in Example 8. It is anticipated that this plasmid can be used for
 transforming yeast cells that can bind a human epidermal growth factor (EGF)
 through an anchored chimeric protein containing an EGF receptor.
- In Figure 18 the composition of plasmids pUR4482 and 4483 is indicated. Their preparation is described in Example 9. Plasmid pUR4482 is a yeast episomal expression plasmid for expression of a fusion protein with the invertase signal sequence, the CH_V09 variable region, the Myc-tail, and the "X-P-X-P" Hinge region of a camel antibody, and the α-agglutinin cell wall anchor region. Plasmid pUR4483
 - differs from pUR4482 in that it does not contain the "X-P-X-P" Hinge region.

 In Figure 19 immunofluorescent labelling (anti-Myc antibody) of SU10 cells in the exponential phase (OD₅₃₀=0.5) expressing the genes of camel antibodies present on plasmids pUR4424, pUR4482 and pUR4483 is shown.
 - Ph = phase contrast, Fl = fluorescence.

In Figure 20 immunofluorescent labelling (anti-human IgG antibody) of SU10 cells in the exponential phase ($OD_{530}=0.5$) expressing the genes of camel antibodies present on plasmids pUR4424, pUR4482 and pUR4483 is shown.

Ph = phase contrast, Fl = fluorescence.

Detailed description of the invention

The present invention relates to the isolation of valuable compounds from complex mixtures by making use of immobilized ligands. The immobilized ligands can be proteins obtainable via genetic engineering and can consist of two parts, namely both an anchoring protein or functional part thereof and a binding protein or functional part thereof.

The anchoring protein sticks into cell walls of microorganisms, preferably lower eukaryotes, e.g. yeasts and moulds. Often this type of proteins has a long C-terminal part that anchors it in the cell wall. These C-terminal parts have very special amino acid sequences. A typical example is anchoring via C-terminal sequences of proteins enriched in proline, see Kok (1990).

The C-terminal part of these anchoring proteins can contain a substantial number of potential serine and threonine glycosylation sites. O-glycosylation of these sites gives a rod-like conformation to the C-terminal part of these proteins.

In the case of anchored manno-proteins they seem to be linked to the glucan in the cell wall of lower eukaryotes, as they cannot be extracted from the cell wall with sodium dodecyl sulphate (SDS), but can be liberated by glucanase treatment, see our co-pending patent application WO-94/01567 (UNILEVER) published 20 January 1994 and Schreuder c.s. (1993), both being published after the claimed priority date. Another mechanism to anchor proteins at the outer side of a cell is to make use of the property that a protein containing a glycosyl-phosphatidyl-inositol (GPI) group

The <u>binding protein</u> is so called, because it ligates or binds to the specific compound to be isolated. If the N-terminal part of the anchoring protein is sufficiently capable of binding to a specific compound, the anchoring protein itself can be used in a process for isolating that specific compound. Suitable examples of a binding protein comprise an antibody, an antibody fragment, a combination of antibody fragments, a receptor protein, an inactivated enzyme still capable of binding the corresponding substrate, and a peptide obtained via Applied Molecular Evolution, see Lewin (1990), as well as a part of any of these proteinaceous substances still capable of

anchors via this GPI group to the cell surface, see Conzelmann c.s. (1990).

15

. 20

binding to the specific compound to be isolated. All these binding proteins are characterized by specific recognition of the compounds or group of related compounds to be isolated. The binding rate and release rate, and therefore the binding constant between the specific compound to be isolated and the binding protein, can be regulated either by changing the composition of the liquid extract in which the compound is present or, preferably, by changing the binding protein by protein engineering.

The gene coding for the chimeric protein comprising both the binding protein and the anchoring protein (or functional parts thereof) can be placed under control of a constitutive, inducible or derepressible promoter and will generally be preceded by a DNA fragment encoding a signal sequence ensuring efficient secretion of the chimeric protein. Upon secretion the chimeric protein will be anchored in the cell wall of the microorganisms, thereby covering the surface of the microorganisms with the chimeric protein. These microorganisms can be obtained in normal fermentation processes and their isolation is a cheap process, when physical separation processes are used, e.g. centrifugation or membrane filtration.

After washing, the isolated microorganisms can be added to liquid extracts containing the valuable specific compound or compounds. After some time the equilibrium between the bound and free specific compound(s) will be reached and the microorganisms to which the specific compound or group of related compounds is bound can be separated from the extract by simple physical techniques. Alternatively, the microorganisms covered with ligands can be brought on a support material and subsequently this coated support material can be used in a column.

The liquid extract containing the specific compound or compounds of interest can be added to the column and afterwards the compound(s) can be released from the ligand by changing the composition of the eluting liquid or the temperature or both. A skilled person will recognize that in addition to these two possibilities other modifications can be used for effecting the binding of the specific compound and the ligand, their subsequent isolation and/or the release of the specific compound(s). In particular the invention relates to chimeric proteins that are bound to the cell wall of lower eukaryotes. Suitable lower eukaryotes comprise yeasts, e.g. Candida,

Debaryomyces, Hansenula, Kluyveromyces, Pichia and Saccharomyces, and moulds e.g. Aspergillus, Penicillium and Rhizopus. For some applications prokaryotes are also applicable, especially Gram-positive bacteria, examples of which include lactic acid bacteria, and bacteria belonging to the genera Bacillus and Streptomyces.

5

20

30

For <u>lower eukaryotes</u> the present invention provides genes encoding chimeric proteins consisting of:

- a. a DNA sequence encoding a signal sequence functional in a lower eukaryotic host, e.g. derived from a yeast protein including the α -mating factor, invertase,
- 10 α-agglutinin, inulinase or derived from a mould protein e.g. xylanase;
 - b. a structural gene encoding a C-terminal part of a cell wall protein preceded by a structural gene encoding a protein, that is capable of binding to the specific compound or group of compounds of interest, examples of which include
 - an antibody,
- a single chain antibody fragment (scFv; see Bird and Webb Walker (1991),
 - a variable region of the heavy chain (V_H) or a variable region of the light chain (V_L) of an antibody or that part of such variable region still containing one to three of the complementarity determining regions (CDRs),
 - an agonist-recognizing part of a receptor protein or a part thereof still capable of binding the agonist,
 - a catalytically inactivated enzyme, or a fragment of such enzyme still containing a substrate binding site of the enzyme,
 - specific lipid binding proteins or parts of these proteins still containing the lipid binding site(s), see Ossendorp (1992), and
- a peptide that has been obtained via Applied Molecular Evolution, see Lewin (1990).

All expression products of these genes are characterized in that they consists of a signal sequence and both a protein part, that is capable of binding to the compound(s) to be isolated, and a C-terminus of a typically cell wall bound protein, examples of the latter including α-agglutinin, see Lipke c.s. (1989), a-agglutinin, see Roy c.s. (1991), FLO1 (see Example 5 and SEQ ID NO: 14) and the Major Cell

Wall Protein of lower eukaryotes, which C-terminus is capable of anchoring the expression product in the cell wall of the lower eukaryote host organism.

The expression of these genes encoding chimeric proteins can be under control of a constitutive promoter, but an inducible promoter is preferred, suitable examples of which include the GAL7 promoter from Saccharomyces, the inulinase promoter from Kluyveromyces, the methanol-oxidase promoter from Hansenula, and the xylanase promoter of Aspergillus. Preferably the constructs are made in such a way that the new genetic information is integrated in a stable way in the chromosome of the host cell, see e.g. WO-91/00920 (UNILEVER).

The lower eukaryotes transformed with the above mentioned genes can be grown in normal fermentation, continous fermentation, or fed batch fermentation processes.

The selection of a suitable process for growing the microorganism will depend on the construction of the gene and the promoter used, and on the desired purity of the cells after the physical separation procedure(s).

15

20

For <u>bacteria</u> the present invention deals with genes encoding chimeric proteins consisting of:

- a. a DNA sequence encoding a signal sequence functional in the specific bacterium,
 e.g. derived from a Bacillus α-amylase, a Bacillus subtilis subtilisin, or a
 Lactococcus lactis subsp. cremoris proteinase;
- b. a structural gene encoding a C-terminal part of a cell wall protein preceded by a structural gene encoding a protein capable of binding to the specific compound or group of compounds of interest, examples of which are given above for a lower eukaryote.
- All expression products of these genes are characterized in that they consist of a signal sequence and both a protein part, that is capable of binding to the specific compound or specific group of compounds to be isolated, and a C-terminus of a typically cell wall-bound protein such as the proteinase of *Lactococcus lactis* subsp. cremoris strain Wg2, see Kok c.s. (1988) and Kok (1990), the C-terminus of which is capable of anchoring the expression product in the cell wall of the host bacterium.

The invention is illustrated with the following Examples without being limited thereto. First the endonuclease restriction sites mentioned in the Examples are given.

Example 1. Construction of a gene encoding a chimeric protein that will be anchored in the cell wall of a lower eukaryote and is able to bind with high specificity lysozyme from a complex mixture.

Lysozyme is an anti-microbial enzyme with a number of applications in the pharmaceutical and food industries. Several sources of lysozyme are known, e.g. egg yolk or a fermentation broth containing a microorganism producing lysozyme.

- Monoclonal antibodies have been raised against lysozyme, see Ward c.s. (1989), and the mRNA's encoding the light and heavy chains of such antibodies have been isolated from the hybridoma cells and used as template for the synthesis of cDNA using reverse transcriptase. Starting from the plasmids as described by Ward c.s. (1989), we constructed a pEMBL-derived plasmid, designated pUR4122, in which the multiple cloning site of the pEMBL-vector, ranging from the EcoRI to the HindIII site, was replaced by a 231 bp DNA fragment, whose nucleotide sequence is given in SEQ ID NO: 1 and has an EcoRI site (GAATTC) at nucleotides 1-6, a PstI site (CTGCAG) at nucleotides 105-110, a BstEII site (GGTCACC) at nucleotides 122-128, a XhoI site (CTCGAG) at nucleotides 207-212, and a HindIII site
- 35 (AAGCTT) at nucleotides 226-231.

Construction of pUR4122

Plasmid pEMBL9, see Dente c.s. (1983), was digested with EcoRI and HindIII and the resulting large fragment was ligated with the double stranded synthetic DNA fragment given in SEQ ID NO: 1. For the successive ligation of DNA fragments, 5 which finally form the coding sequence of a single chain antibody fragment for lysozyme, the following elements were combined in the 231 bp DNA fragment (SEQ 1D NO: 1) inserted into the pEMBL-9 vector: the 3' part of the GAL7 promoter, the invertase signal sequence (SUC2), a Pstl restriction site, a BstEII restriction site, a sequence encoding the (GGGGS)x3 peptide linker connecting the V_Hand V_L frag-10 ments, a Sucl restriction site, a Xhol restriction site and a HindIII restriction site, resulting in plasmid pUR4119. To obtain the in frame fusion between V_H and the GGGGS-linker plasmid pSW1-VHD1.3-VKD1.3-TAG1, see Ward c.s. (1989), was digested with Pstl and BstEll and a DNA fragment of 0.35 kbp was ligated in the correspondingly digested pUR4119 resulting in plasmid pUR4119A. Subsequently the plasmid pSW1-VHD1.3-VKD1.3-TAG1 was digested with Sacl and Xhol and this fragment containing the coding part of V_L was finally ligated into the Sacl/Xhol sites of pUR4119A, resulting in plasmid pUR4122 (see Figure 1).

Construction of pUR4174, see Figure 4

- To obtain S. cerevisiae episomal expression plasmids containing DNA encoding a cell wall anchor derived from the C-terminal part of α-agglutinin, plasmid pUR2741 (see Figure 2) was selected as starting vector. Basically, this plasmid is a derivative of pUR2740, which is a derivative of plasmid pUR2730 as described in WO-91/19782 (UNILEVER) and by Verbakel (1991). The preparation of pUR2730 is clearly described in Example 9 of EP-A1-0255153 (UNILEVER). Plasmid pUR2741 differs from plasmid pUR2740 in that the Eagl restriction site within the remaining part of the already inactive test resistance gene was deleted through Nrul/Sall digestion. The Sall site was filled in prior to religation.
- 30 After digesting pUR4122 with Sac1 (partially) and HindIII, the approximately 800 bp fragment was isolated and cloned into the pUR2741 vector fragment, which was

obtained after digestion of pUR2741 with the same enzymes. The resulting plasmid was named pUR4125.

A plasmid named pUR2968 (see Figure 3) was made by (1) digesting with HindIII the $Ag\alpha I$ -containing plasmid pL α 21 published by Lipke c.s. (1989), (2) isolating an about 6.1 kbp fragment and (3) ligating that fragment with HindIII-treated pEMBL9, so that the 6.1 kbp fragment was introduced into the HindIII site present in the multiple cloning site of the pEMBL9 vector.

Plasmid pUR4125 was digested with XhoI and HindIII and the about 8 kbp fragment was ligated with the approximately 1.4 kbp NheI-HindIII fragment of

10 pUR2968, using Xhol/Nhel adapters having the following sequence:

XhoI NheI
$$5'-\text{TC GAG}$$
 ATC AAA GGC GGA TCT G -3' = SEQ ID NO: 2 $3'-$ C TAG TTT CCG CCT AGA $CGATC-5'$ = SEQ ID NO: 3.

The plasmid resulting from the ligation of the appropriate parts of plasmids

pUR2968, pUR4125 and Xhol/NheI adapters, was designated pUR4174 and encodes
a chimeric fusion protein at the amino terminus consisting of the invertase signal

(pre) peptide, followed by the scFv-LYS polypeptide and, finally, the C-terminal part
of α-agglutinin (see Figure 4).

20 Construction of pUR4175, see Figure 4

Upon digesting pUR4122 (see above) with Pstl and Hindlll, the approximately 700 bp fragment was isolated and ligated into a vector fragment of plasmid pSY16, see Harmsen c.s. (1993), which was digested with Eagl and Hindlll and using Eagl-Pstl adapters, having the following sequence:

25
$$EagI$$
 $pstI$ = SEQ ID NO: 4
5'- G GCC CAG GTG CAG CTG CA-3' = SEQ ID NO: 5
3'- CGG GTC CAC GTC GG -5' = SEQ ID NO: 5

The resulting plasmid, named pUR4132, was digested with Xhol and HindIII and ligated with the approximately 1.4 kbp NheI-HindIII fragment of pUR2968 (see above), using Xhol/Nhel adapters as described above, resulting in pUR4175 (see Figure 4). This plasmid contains a gene encoding a chimeric protein consisting of the α-mating factor prepro-peptide, followed by the scFv-LYS polypeptide and, finally, the C-terminal part of α-agglutinin.

- Example 2. Construction of genes encoding a series of homologous chimeric proteins that will be anchored in the cell wall of a lower eukaryote and are able to bind with high specificities the musk fragrance trascolide® from a complex mixture.
- The isolation of RNA from the hybridoma cell lines, the preparation of cDNA and amplification of gene fragments encoding the variable regions of antibodies by PCR was performed according to standard procedures known from the literature, see e.g. Orlandi c.s. (1989). For the PCR amplification different oligonucleotide primers have been used.
- 10 For the heavy chain fragment:

A: AGG TSM ARCTGC AGS AGT CWG G = SEQ ID NO: 6 Pst1

in which S is C or G, M is A or C, R is A or G, and W is A or T, and

15 B: TGA GGA GAC GGT GAC CGT GGT CCC TTG GCC CC

Bst Ell = SEQ ID NO: 7.

For the light chain fragment (Kappa):

C: GAC ATT GAG CTC ACC CAG TCT CCA = SEQ ID NO: 8, Sacl

20 and

D: GTT TGA TCT CGA GCT TGG TCC C = SEQ ID NO: 9. Xhol

Construction of pUR4143

- To simplify future construction work an Eagl restriction site was introduced in pUR4122 (see above), at the junction between the invertase signal sequence and the scFv-LYS. This was achieved by replacing the about 110 bp EcoRI-PstI fragment within the synthetic fragment given in SEQ ID NO: 1 by synthetic adapters with the following sequence:
- 30 EcoRI PstI = SEQ ID NO: 10 GCGGCAAGTCCACGTCG = SEQ ID NO: 11.

15

The resulting plasmid was designated pUR4122.1: a construction vector for single chain Fv assembly in frame behind an Eagl site for expression behind either the prepro- α -mating factor sequence or the SUC2 invertase signal sequence.

After digesting the heavy chain PCR fragment with Pstl and BstEll, two fragments were obtained: a Pstl fragment of about 230 bp and a Pstl/BstEll fragment of about 110 bp. The latter fragment was cloned into vector pUR4122.1, which was digested with Pstl and BstEll. The newly obtained plasmid (pUR4122.2) was digested with Sacl and Xhol, after which the light chain PCR fragment (digested with the same restriction enzymes) was cloned into the vector, resulting in pUR4122.3. This

plasmid was digested with PstI, after which the above described about 230 bp PstI fragment was cloned into the plasmid vector, resulting in a plasmid called pUR4143. Two orientations are possible, but selection can be made by restriction analysis, as usual. Instead of the scFv-LYS gene originally present in pUR4122, this new plasmid pUR4143 contains a gene encoding an scFv-TRAS fragment of anti-traseolide antibody 02/01/01 (for the nucleotide sequence of the 714 bp PstI-XhoI fragment see SEQ ID NO: 12).

Construction of pUR4178 and pUR4179.

After digesting pUR4143 with Eagl and with HindIII, an about 715 bp fragment can be isolated. Subsequentely, this fragment can be cloned into the vector backbone fragments of pUR2741 and pUR4175, that were digested with the same restriction enzymes. In the case of pUR2741, this resulted in plasmid pUR2743.4 (see Figure 5). This plasmid can subsequently be cleaved with Xhol and HindIII and ligated with the about 8 kbp Xhol-HindIII fragment of pUR4174, resulting in pUR4178 (see

25 Figure 6).

In the situation where pUR4175 was used as a starting vector, the resulting plasmid was designated pUR4179 (see Figure 7).

Both plasmids, pUR4178 and pUR4179 were introduced into S. cerevisiae.

Example 3. The modification of the binding parts of the chimeric protein that can bind traseolide® in order to improve the binding or release of traseolide® under certain conditions.

Modification of binding properties of antibodies during the immune response is a well known immunological phenomenon originating from the fine tuning of complementarity determining sequences in the antibody's binding region to the antigen's molecular properties. This phenomenon can be mimicked *in vitro* by adjusting the antigen binding regions of antibody fragments based on molecular models of these regions in contact with the antigen.

One such example consists of protein engineering the antimusk antibody M02/01/01 to a stronger binding variant M020501i.

First, a molecular model of M02/01/01 variable fragment (Fv) was constructed by homology modelling, using the coordinates of the anti-lysozyme antibody HYHEL- 10 as a template (Brookhaven Protein Data Bank entry: 3HFM). This model was refined using Molecular Mechanics and Molecular Dynamics methods from within the Biosym program DISCOVER, on a Silicon Graphics 4D240 workstation. Secondly, the binding site of the resulting Fv was mapped by visually docking the musk antigen into the CDR region, followed by a refinement using molecular dynamics again. Upon inspection of the resulting model for packing efficiency (van der Waals contact areas), it was concluded that substitution of ALA H96 by VAL would increase the (hydrophobic) contact area between the ligand and Fv, and consequently lead to a stronger interaction (see Figure 8).

When this mutation is introduced into M02/01/01, the cDNA-derived scFv from Example 2, the result will be Fv M020501i; a variant with an increased affinity of at least a factor of 5 can be expected, and the increased affinity could be measured using fluorescence titration of the Fv with the musk odour molecule.

25

Example 4. Construction of a gene encoding a chimeric protein that will be anchored in the cell wall of lower eukaryote and is able to bind hormones such as HCG.

Gene fragments, encoding the variable regions of the heavy and light chain
fragments from the monoclonal antibody directed against the human chorionic
gonadotropin were obtained from a hybridoma cell line in a similar way as described
in Example 2.

Subsequently, these HCG V_H and V_L gene fragments were cloned into plasmid pUR4143 by replacing the corresponding Pstl-BstEll and Sacl- Xhol gene fragments, resulting in plasmid pUR4146.

Similar to the method described in Example 2, the 734 bp Eagl-XhoI fragment (nucleotide sequence given in SEQ ID NO: 13) encoding the variable regions of the heavy and light chain fragments from the monoclonal antibody directed against the human chorionic gonadotropin (an scFv-HCG fragment) was isolated from pUR4146 and was introduced into the vector backbone fragment of pUR4178 (see Example 2) and will be introduced into the vector backbone fragment of pUR4175 (see Example 1), both digested with the same restriction enzymes. The resulting plasmids pUR4177 (see Figure 9) was, and pUR4180 (see Figure 10) will be, introduced into S. cerevisiae strain SU10.

20

15

- Example 5. Construction of a gene encoding a chimeric scFv-FLO1 protein that will be anchored in the cell wall of lower eukaryote and is able to bind hormones such as HCG.
- One of the genes associated with the flocculation phenotype in S. cerevisiae is the FLO1 gene. The DNA sequence of a clone containing major parts of the FLO1 gene has been determined, see SEQ ID NO: 14 giving 2685 bp of the FLO1 gene. The cloned fragment appeared to be approximately 2 kb shorter than the genomic copy as judged from Southern and Northern hybridizations, but encloses both ends of the FLO1 gene. Analysis of the DNA sequence data indicates that the putative protein contains at the N-terminus a hydrophobic region which confirms a signal sequence for secretion, a hydrophobic C-terminus that might function as a signal for the

attachment of a GPI-anchor and many glycosylation sites, especially in the C-terminus, with 46.6% serine and threonine in the arbitrarily defined C-terminus (aa 271-894). Hence, it is likely that the FLO1 gene product is located in an orientated fashion in the yeast cell wall and may be directly involved in the process of interaction with neighbouring cells. The cloned FLO1 sequence might therefore be suitable for the immobilization of proteins or peptides on the cell surface by a different type of cell wall anchor. For the production of a chimeric protein comprising the scFv-HCG followed by the C-terminal part of the FLO1-protein, plasmid pUR2990 (see Figure 11) can be used as a starting vector. The preparation of episomal plasmid pUR2990 was described in 10 our co-pending patent application WO-94/01567 (UNILEVER) published on 20 January 1994, i.e. during the priority year. Plasmid pUR2990 comprises the chimeric gene consisting of the gene encoding the Humicola lipase and a gene encoding the putative C-terminal cell wall anchor domain of the FLO1 gene product, the chimeric gene being preceded by the invertase signal sequence (SUC2) and the GAL7 15 promoter; further the plasmid comprises the yeast 2 µm sequence, the defective Leu2 promoter described by Eckard and Hollenberg (1983), and the Leu2 gene, see Roy c.s. (1991). Plasmid pUR4146, described in Example 4, can be digested with Pstl and Xhol, and the about 0.7 kbp Pstl-Xhol fragment containing the scFv-HCG coding sequence can be isolated. For the in frame fusion of this DNA sequence 20 between the C-terminal FLO1 part and the SUC2 signal sequence, the fragment can be directly ligated with the 9,3 kbp Eagl/NheI (partial) backbone of plasmid pUR2990, resulting in plasmid pUR4196 (see Figure 12). This plasmid will comprise an additional triplet encoding Ala at the transition between the SUC2 signal sequence and the start of the scFv-HCG, and a E-I-K-G-G amino acid sequence in 25

If in the previous Examples 1-5 the level of exposed antibody fragments is too low, the production level can be increased by mutagenesis of the frame work regions of the antibody fragment. This can be done in a site directed way or by (targeted) random mutagenesis, using techniques described in the literature.

front of the first amino acid (Ser) of the C part of FLO1 protein.

cho01pcr

35

Example 6. Construction of a gene encoding a chimeric protein that will be anchored in the cell wall of a lower eukaryote and is able to bind cholesterol.

In the literature two DNA sequences for cholesterol oxidase are described, the choB gene from Brevibacterium sterolicum, see Ohta c.s. (1991) and the choA gene from Streptomyces sp. SA-COO, see Ishizaka c.s. (1989). For the construction of a DNA fusion between the choB gene coding for cholesterol oxidase (EC 1.1.3.6) and the 3' part of the AG-α1 gene, the PCR technique on chromosomal DNA can be applied. Chromosomal DNA can be isolated by standard techniques from Brevibacterium sterolicum, and the DNA part coding for the mature part of the cholesterol oxidase can be amplified through application with the following

cholesterol oxidase can be amplified through application with the following corresponding PCR primers cho01pcr and cho02pcr:

Both primers can specifically hybridize with the target sequence, thereby amplifying the coding part of the gene in such a way, that the specific PCR product -after

Proteinase K treatment and digestion with EcoRI and HindIII- can be directly cloned into a suitable vector, here preferably pTZ19R, see Mead c.s. (1986). This will result in plasmid pUR2985 (see Figure 13).

In addition to the already mentioned restriction sites both PCR primers generate other restriction sites at the 5' end and the 3' end of the 1.5 kbp DNA fragment, which can be used later on to fuse the fragment in frame between either the SUC2 signal sequence or the prepro- α -mating factor signal sequence on one side and the C-terminus coding part of the α -agglutinin gene on the other side. To facilitate the ligation behind the prepro-MF sequence a *Not*1 site is introduced at the 5' end of

PCR oligonucleotide cho01pcr, allowing for example, the exchange of the 731 bp Eagl/Nhel fragment containing the scFv-Lys coding sequence in pUR4175 for the choB coding sequence.

To create an enzymatically inactive fusion protein between cholesterol oxidase and α-agglutinin, the above described subcloning into pTZ19R can be used. Cholesterol oxidase is an FAD-dependent enzyme for which the crystal structure of the Brevibacterum sterolicum enzyme has been determined, see Vrielink c.s. (1991). The enzyme displays homology with the typical pattern of the FAD-binding domain with the Gly-X-Gly-X-X-Gly sequence near the N-terminus (amino acid 18-23). Site-directed in vitro mutagenesis on the plasmid pUR2985 according to the manufacturer's protocol (Muta-Gene kit, Bio-Rad) can be applied to inactivate the FAD-binding site through replacing the triplet(s) encoding the Gly residue(s) by triplets encoding other amino acids, thereby presumably inactivating the enzyme. E.g. the following primer can be used for site-directed mutagenesis of 2 of the conserved Gly residues.

25

35

As a result of the mutagenesis with the described primer, plasmid pUR2986 will be obtained. From this plasmid the DNA coding for the presumably inactivated cholesterol oxidase can be released as a 1527 bp fragment through Notl/Nhel digestion, and subsequently directly used to exchange the scFv-Lys coding sequence in pUR4175, thereby generating plasmid pUR2987 (see Figure 14). To obtain a variant yeast secretion vector, where the secretion is directed through the SUC2 signal sequence, for example the 1823 bp long Sacl/Nhel segment of plasmid pUR2986 can be used to replace the Sacl/Nhel fragment in pUR4174.

This inactivation of the FAD-binding site might be preferable over other mutations, since an unchanged active centre can be expected to leave the binding properties of cholesterol oxidase for cholesterol unaltered. Instead of the described Gly-Ala

exchanges at position 18 and 20 of the mature coding sequence, every other suitable amino acid change can also be performed.

To inactivate the enzyme, site directed mutagenesis can be optionally immediately performed in the active site cavity, for example through exchange of the Glu331, a residue appropriately positioned to act as the proton acceptor, thus generating a new variant of an immobilized, enzymatically inactive fusion protein.

Example 7. Construction of a gene encoding a chimeric protein that will be anchored in the cell wall of a lactic acid bacterium and is able to bind cholesterol.

It has been described that proteinase of Lactococcus lactis subsp. cremoris is anchored to the cell wall through its 127 amino acid long C-terminal, see Kok c.s. (1988) and Kok (1990). In a way similar to that described in Example 6, the cholesterol oxidase of Brevibacterium sterolicum (choB) can be immobilized on the surface of Lactococcus lactis. Fusions can be made can be made between the choB structural gene and the N-terminal signal sequence and the C-terminal anchor of the proteinase of Lactococcus lactis. Plasmid pGKV550 (see Figure 15) contains the complete proteinase operon of Lactococcus lactis subsp. cremoris Wg2, including the promoter, a ribosome binding site and DNA fragments encoding the already mentioned signal and anchor sequences, see Kok (1990). First a DNA fragment, containing the main part of the signal sequence, flanked by a ClaI site and an EagI site can be constructed with PCR on pGKV550 as follows:

25 Primer prt1:

35

5'-AA GAT CTA TCG ATC TTG TTA GCC GGT ACA-3' = SEQ ID NO: 24

= SEQ ID NO: 26 = SEQ ID NO: 27

Primer prt2: - SEQ 1D NO 3'-CAG CCG CTT TAG GTT CGT TGC CGG CCC CCC TTC GAA CCC-5' Eagl HindIII After the PCR reaction as described in Example 6, the 98 bp long PCR fragment can be isolated and digested with Clal and HindIII. pGKV550 can subsequently be cleaved partially with Clal and completely with HindIII, after which digestions the vector fragment, containing the promoter, the ribosome binding site, the DNA

fragment encoding the N-terminal 8 amino acids and the cell wall binding fragment containing the 127 C-terminal amino acids of the proteinase gene can be isolated on gel.

A copy of the cholesterol oxidase gene, suitable for fusion with the prtP anchor domain can be produced by a PCR reaction using plasmid pUR2985 (Example 6) as template and a combination of primer cho01pcr (see Example 6) and the following primer cho03pcr instead of primer cho02pcr:

The about 1.53 kbp fragment generated by this reaction can be digested with Not1 and HindIII to produce a molecule which can subsequently be ligated with the large Eagl/HindIII fragment from pUR2988 (see Figure 16). The resulting plasmid,

20 pUR2989, will contain the cholesterol oxidase coding sequence inserted between the signal sequence and the C-terminal cell wall anchor domain of the proteinase gene. After introduction into Lactobacillus lactis subsp. lactis MG1363 by electroporation, this plasmid will express cholesterol oxidase under control of the proteinase promoter. The transport through the membrane will be mediated by the proteinase signal sequence and the immobilization of the cholesterol oxidase by the proteinase anchor. As it is unlikely that the Lactococcus will secrete FAD as well, the

30 Example 8. Construction of a gene encoding a chimeric protein that will be anchored in the cell wall of a lower eukaryote and is able to bind growth hormones, such as the epidermal growth factor.

cholesterol oxidase will not be active but will be capable to bind cholesterol.

For the isolation of larger amounts of human epidermal growth factor (EGF) the corresponding receptor can be used in form of a fusion between the binding domain

25

and a C-terminal part of α -agglutinin as cell wall anchor. The complete cDNA sequence of the human epidermal growth factor is cloned and sequenced. For the construction of a fusion protein with EGF binding capacity the N-terminal part of the mature receptor until the central 23 amino acids transmenbrane region can be utilized.

The plasmid pUR4175 can be used for the construction. Through digestion with Eagl and Nhel (partial) a 731 bp DNA fragment containing the sequence coding for scFv is released and can be replaced by a DNA fragment coding for the first 621 amino acids of human epidermal growth factor receptor. Initiating from an existing human cDNA library or otherwise through production of a cDNA library by standard techniques from preferentially EGF receptor overexpressing cells, e.g. A431 carcinoma cells, see Ullrich c.s. (1984), further PCR can be applied for the generation of in frame linkage between the extracellular binding domain of the human growth factor receptor (amino acid 1-622) and the C-terminal part of α-agglutinin.

PCR oligonucleotides for the in frame linkage of human epidermal growth factor receptor and the C-terminus of α -agglutinin.

 actracellular binding domain of EGF receptor and the C terminal part of
 α-agglutinin.

25

This fusion would result in an addition of 2 Ala amino acids between the signal sequence and the mature N-terminus of EGF receptor.

The newly obtained 1.9 kbp PCR fragment can be digested with Not1 and Nhel and directly ligated into the vector pUR4175 after digesting with the same enzymes, resulting in plasmid pUR2993 (see Figure 17), comprising the GAL7 promoter, the prepro-α-mating factor sequence, the chimeric EGF receptor binding domain gene / α-agglutinin gene, the yeast 2 μm sequence, the defective LEU2 promoter and the LEU2 gene. This plasmid can be transformed into S. cerevisiae and the transformed cells can be cultivated in YP medium whereby expression of the chimeric protein can be induced by adding galactose to the medium.

Example 9. Construction of genes encoding a chimeric protein anchored to the cell wall of yeast, comprising a binding domain of a "Camelidae" heavy chain antibody

Recently it was described that camels as well as a number of related species (e.g. lamas) contain a considerable amount of lgG antibody molecules which are only composed of heavy-chain dimers, see Hamers-Casterman c.s. (1993). Although these "heavy-chain" antibodies are devoid of light chains, it was demonstrated, that they nevertheless have an extensive antigen-binding repertoire. In order to show that the variable regions of this type of antibodies can be produced and will be linked to the exterior of the cell wall of a yeast, the following constructs were prepared.

30 Construction of pUR2997, pUR2998 and pUR2999

The about 2.1 kbp Eagl-Hindlll fragment of pUR4177 (Example 4, Fig 9) was isolated. By using PCR technology, an EcoRI restriction site was introduced immediately upstream of the Eagl site, whereby the C of the EcoRI site is the same as the first C of the Eagl site. The thus obtained EcoRI-HindllI fragment was

ligated into plasmid pEMBL9, which was digested with EcoR1 and Hind111, which resulted in pUR4177.A

The EcoRI/Nhel fragment of plasmid pUR4177.A was replaced by the EcoRI/Nhel fragments of three different synthetic DNA fragments (SEQ ID NO: 32, SEQ ID NO: 33, and SEQ ID NO: 34) resulting in pUR2997, pUR2998 and pUR2999, respectively. The about 1.5 kbp BstEll-Hindlll fragments of pUR2997 and pUR2998

Construction of pUR4421

were isolated.

- The multiple cloning site of plasmid pEMBL9, see Dente c.s. (1983), (ranging from the EcoR1 to the HindIII site) was replaced by a synthetic DNA fragment having the nucleotide sequence given below, see SEQ ID NO: 35 giving the coding strand and SEQ ID NO: 36 giving the non-coding strand. The 5'-part of this nucleotide sequence comprises an Eagl site, the first 4 codons of a Camelidae V_H gene
- fragment (nucleotides 16-27) and a Xhol site (CTCGAG) coinciding with codons 5 and 6 (nucleotides 28-33). The 3'-part comprises the last 5 codons of the Camelidae V_H gene (nucleotides 46-60) (part of which coincides with a BstEII site), eleven codons of the Myc tail (nucleotides 61-93), see SEQ ID NO: 35 containing these eleven codons and SEQ ID NO: 37 giving the amino acid sequence, and an EcoRI
- site (GAATTC). The EcoRI site, originally present in pEMBL9, is not functional any more, because the 5'- end of the nucleotide sequence contains AATTT instead of AATTC, indicated below as (EcoRI). The resulting plasmid is called pUR4421. The Camelidae V_H fragment starts with amino acids Q-V-K and ends with amino acids V-S-S.

- OF THE PROPERTY OF THE PROPERT

Construction of pUR4424

After digesting the plasmid pB09 with Xhol and BstEII, a DNA fragment of about 0.34 kbp was isolated from agarose gel. This fragment codes for a truncated V_H fragment, missing both the first 4 and the last 5 amino acids of the Camelidae V_H fragment. Plasmid pB09 was deposited as E. coli JM109 pB09 at the Centraal Bureau voor Schimmelcultures, Baarn on 20 April 1993 with deposition number CBS 271.93. The DNA and amino acid sequences of the Camel V_H fragments followed by the Flag sequence as present in plasmid pB09 were given in Figure 6B of European patent application 93201239.6 (not yet published), which is herein incorporated by reference. The obtained about 0.34 kbp fragment was cloned into pUR4421. To this end plasmid pUR4421 was digested with Xhol and HindIII, after which the about 4 kb vector fragment was isolated from an agarose gel. The resulting vector was ligated with the about 0.34 kbp XhoI/BstEII fragment and a synthetic DNA linker having the following sequence:

15	BstEII	<i>Hin</i> dIII				
	<u>GTCACC</u> GTCTCCTCAT	raatg <u>a</u>	=	SEQ ID	NO:	38
GCAGAGGAGTATTACTTCGA		• =	SEQ ID	NO:	39	

resulting in plasmid pUR4421-09.

Plasmid pSY16 was digested with EagI and HindIII, after which the about 6.5 kbp long vector backbone was isolated and ligated with the about 0.38 kbp EagI/HindIII fragment from pUR4421-09 resulting in pUR4424.

Construction of pUR4482 and pUR4483

- From pUR4424 the about 0.44 kbp SacI-BstEII fragment, coding for the invertase signal sequence and the camel heavy chain variable 09 (= CH_v09) fragment, was isolated as well as the about 6.3 kbp SacI-HindIII vector fragment. The about 6.3 kbp fragment and the about 0.44 kbp fragment from pUR4424 were ligated with the BstEII-HindIII fragment from pUR2997 or pUR2998 yielding pUR4482 and pUR4483, respectively.
 - Plasmid pUR4482 is thus an yeast episomal expression plasmid for expression of a fusion protein with the invertase signal sequence, the CH_V09 variable region, the Myc-tail and the Camel "X-P-X-P" Hinge region, see Hamers-Casterman c.s. (1993),

(1993), and the α-agglutinin cell wall anchor region. Plasmid pUR4483 differs from pUR4482 in that it contains the Myc-tail but not the "X-P-X-P" Hinge region. Similarly, the BstEll-Hindlll fragment from pUR2999 can be ligated with the about 6.3 kbp vector fragment and the about 0.44 kbp fragment from pUR4424, resulting in pUR4497, which will differ from pUR4482 in that it contains the "X-P-X-P" Hinge region but not the Myc-tail.

The plasmids pUR4424, pUR4482 and pUR4483 were introduced into Saccharomyces cerevisiae SU10 by electroporation, and transformants were selected on plates lacking leucine. Transformants from SU10 with pUR4424, pUR4482 or pUR4483, respectively, were grown on YP with 5% galactose and analysed with immuno-fluorescence microscopy, as described in Example 1 of our co-pending WO-94/01567 (UNILEVER) published on 20 January 1994. This method was slightly modified to detect the chimeric proteins, containing both the camel antibody and the Myc tail, present at the cell surface.

- In one method a monoclonal mouse anti-Myc antibody was used as a first antibody to bind to the Myc part of the chimeric protein; subsequently a polyclonal anti-mouse lg antiserum labeled with fluorescein isothiocyanate (= FITC) ex Sigma, Product No. F-0527, was used to detect the bound mouse antibody and a positive signal was determined by fluorescence microscopy.
- In the other method a polyclonal rabbit anti-human IgG serum, which had earlier been proven to cross-react with the camel antibodies, was used as a first antibody to bind the camel antibody part of the chimeric protein; subsequently a polyclonal anti-rabbit Ig antiserum labeled with FITC ex Sigma, Product No. F-0382, was used to detect the bound rabbit antibody and a positive signal was determined by
- 25 fluorescence microscopy.

30

The results in Figure 19 and Figure 20 show clearly that fluorescence can be observed on those cells in which a fusion protein of the CH_V09 fragment with the α-agglutinin cell wall anchor region is produced (pUR4482 and pUR4483). No fluorescence however, was visible on the cells which produce the CH_V09 fragment without this anchor (pUR4424), when viewed under the same circumstances.

CGGATCCAAG CTTGAGCCTG GATGTCGGAC GAGATGAT

CLAIMS

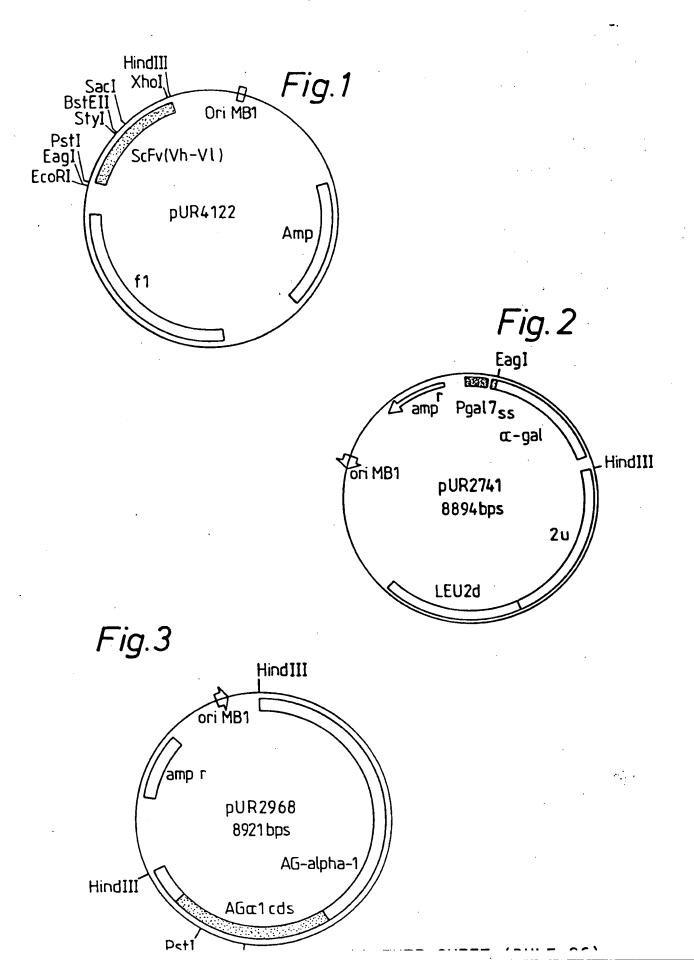

- 1. A method for immobilizing a binding protein capable of binding to a specific compound, comprising the use of recombinant DNA techniques for producing said binding protein or a functional part thereof still having said specific binding capability, said protein or said part thereof being linked to the outside of a host cell, whereby said binding protein or said part thereof is localized in the cell wall or at the exterior of the cell wall by allowing the host cell to produce and secrete a chimeric protein in which said binding protein or said functional part thereof is bound with its C-terminus to the N-terminus of an anchoring part of an anchoring protein capable of anchoring in the cell wall of the host cell, which anchoring part is derivable from the C-terminal part of said anchoring protein.
- 2. The method of claim 1, in which the host is selected from the group consisting of Gram-positive bacteria and fungi.
- 3. The method of claim 2, in which the host is a Gram-positive bacterium selected from the group consisting of lactic acid bacteria, and bacteria belonging to the genera Bacillus and Streptomyces.
- 4. The method of claim 2, in which the host is a fungus selected from the group consisting of yeasts belonging to the genera Candida, Debaryomyces, Hansenula, Kluyveromyces, Pichia and Saccharomyces, and moulds belonging to the genera Aspergillus, Penicillium and Rhizopus.
- 5. A recombinant polynucleotide comprising
 - (i) a structural gene encoding a binding protein or a functional part thereof still having the specific binding capability, and
 - (ii) at least part of a gene encoding an anchoring protein capable of anchoring in the cell wall of a Gram-positive bacterium or a fungus, said part of a gene encoding at least the anchoring part of said anchoring protein, which

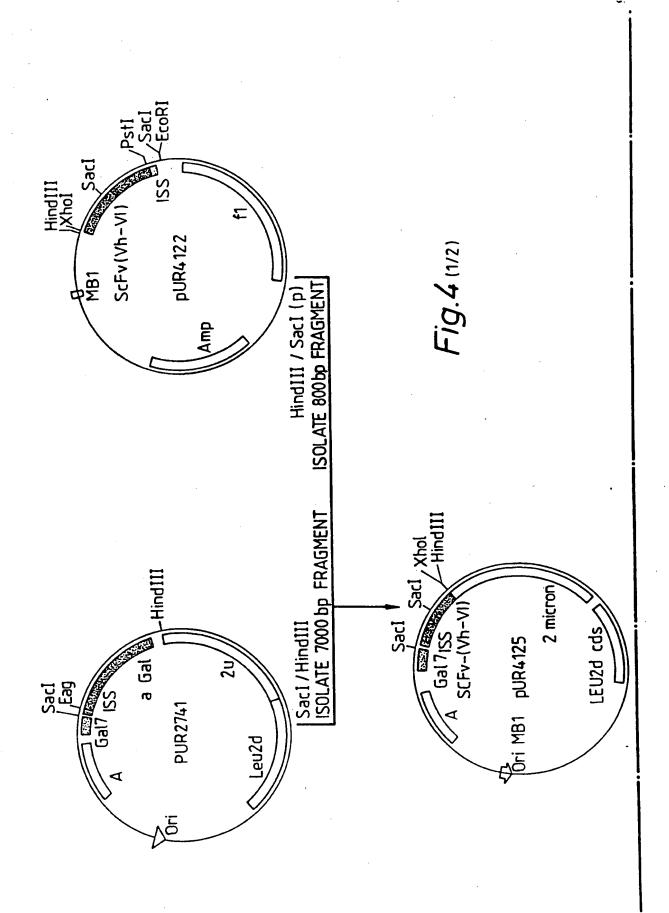

anchoring part is derivable from the C-terminal part of said anchoring protein.

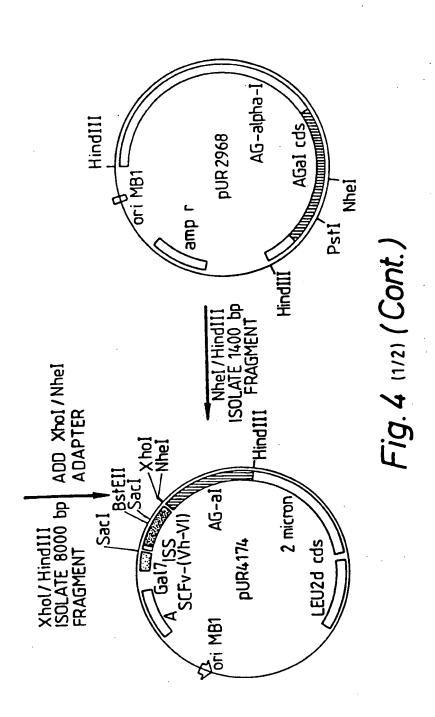

- 6. The polynucleotide of claim 5, wherein the anchoring protein is selected from the group consisting of α -agglutinin, a-agglutinin, FLO1, the Major Cell Wall Protein of a fungus, and proteinase of lactic acid bacteria.
- 7. The polynucleotide of claim 5, further comprising a nucleotide sequence encoding a signal peptide ensuring secretion of the expression product of the polynucleotide.
- 8. The polynucleotide of claim 7, wherein the signal peptide is derived from a protein selected from the group consisting of the α -mating factor of yeast, α -agglutinin of yeast, invertase of Saccharomyces, inulinase of Kluyveromyces, α -amylase of Bacillus, and proteinase of lactic acid bacteria.
- 9. The polynucleotide of any of claims 5-8, operably linked to a promoter, which can be an inducible promoter.
- 10. A recombinant vector comprising a polynucleotide as claimed in any of claims 5-9.
- 11. A chimeric protein encoded by a polynucleotide as claimed in any of claims 5-9.
- 12. A host cell having a cell wall at the outside of its cell and containing at least one polynucleotide as claimed in any of claims 5-9.
- 13. The host cell of claim 12, having at least one polynucleotide as claimed in any of claims 5-9 integrated in its chromosome.

- 14. A host cell having a chimeric protein as claimed in claim 11 immobilized in its cell wall and having the binding protein part of the chimeric protein localized in the cell wall or at the exterior of the cell wall.
- 15. The host cell of any of claims 12-14, which is a fungus selected from the group consisting of yeasts and moulds.
- 16. A process for carrying out an isolation process by using an immobilized binding protein or functional part thereof still capable of binding to a specific compound, wherein a medium containing said specific compound is contacted with a host cell as claimed in any of claims 12-15 under conditions whereby a complex between said specific compound and said immobilized binding protein is formed, separating said complex from the medium originally containing said specific compound and, optionally, releasing said specific compound from said binding protein or functional part thereof.
